15

16 **Abstract**

17 **Study question**:Do the chemotherapeutic regimens of adriamycin, bleomycin,

18 vinblastine and dacarbazine (ABVD),vincristine, etoposide, prednisone, doxorubicin

19 (OEPA) and cyclophosphamide, vincristine, prednisone, dacarbazine (COPDAC)

20 OEPA-COPDAC) used to treat Hodgkin lymphoma, affect the density, morphology

21 and *in vitro* developmental potential of human ovarian follicles?

22

23 **Summary answer**: Ovarian tissue from women treated with ABVD contained a

24 higher density of non-growing follicles/mm^3 and increased numbers of multi-ovular

25 follicles, but showed reduced *in vitro* growth compared with patients with lymphoma

26 who had not received chemotherapy, patients treated with OEPA-COPDAC, age-

27 matched healthy women and age-related model-predicted values.

28

29 **What is known already**: Chemotherapy regimens can cause a loss of follicles within

30 the ovary that depends on the drugs given. Early stage Hodgkin lymphoma is

31 commonly treated by ABVD, a non-alkylating regimen which apparently has ovarian

32 sparing qualities, thus it is important to investigate the histological appearance and

33 distribution of follicles within ABVD-treated ovarian tissue.

34

35 **Study design, size, duration:** Thirteen ovarian biopsies were obtained from

36 Hodgkin lymphoma patients (6 adolescents and 7 adults) and one biopsy from a

37 non-Hodgkin lymphoma patient. Two Hodgkin lymphoma patients and the non-

38 Hodgkin lymphoma patient had received no treatment prior to biopsy collection. The

39 remaining 11 Hodgkin lymphoma patients received one of two regimens; ABVD or

40 OEPA-COPDAC. Tissue was analysed histologically and compared to biopsies from

41 healthy women, and in a sub-group of patients, tissue was cultured for 6 days *in*

42 *vitro.*

43

44 **Participants/materials, setting, methods:** Ovarian biopsies were obtained from

45 patients undergoing ovarian cryopreservation for fertility preservation, and from

46 healthy women at the time of Caesarian section ('obstetric tissue'). Follicle number

47 and maturity were evaluated in sections of ovarian cortical tissue, and compared to

48 an age-related model of mean follicle density and to age-matched contemporaneous

49 biopsies. The developmental potential of follicles was investigated after 6 days tissue

50 culture.

51

52 **Main results and the role of chance**: A total of 6877 follicles was analysed. ABVD-

53 treated tissue contained a higher density of non-growing follicles/mm^3 (230±17)

54 (mean±SEM) than untreated (110±54), OEPA-COPDAC-treated (50±27 and

55 obstetric tissue (20±4)(*P*< 0.01),with follicle density 9-21 standard deviations higher

56 than predicted by an age-related model. Bi-ovular and binucleated non-growing

57 follicles occurred frequently in ABVD-treated and in adolescent untreated tissue but

58 were not observed in OEPA-COPDAC-treated or obstetric tissue, although OEPA-

59 COPDAC-treated tissue contained a high proportion of morphologically abnormal

60 oocytes (52% versus 23% in untreated, 22% in ABVD-treated and 25% in obstetric

61 tissue; *P*< 0.001). Activation of follicle growth *in vitro* occurred in all groups, but in

62 ABVD-treated samples there was very limited development to the secondary stage,

63 whilst in untreated samples from lymphoma patients growth was similar to that

64 observed in obstetric tissue (untreated; $P< 0.01$ versus ABVD-treated, ns versus

65 obstetric).

66

67 **Limitations, reasons for caution:** Although a large number of follicles were

68 analysed, these data were derived from a small number of biopsies. The

69 mechanisms underpinning these observations have yet to be determined and it is

70 unclear how they relate to future fertility.

71

72 **Wider implications of the findings:** This study confirms that the number of non-

73 growing follicles is not depleted following ABVD treatment, consistent with clinical

74 data that female fertility is preserved. Our findings demonstrate that immature follicle

75 density can increase as well as decrease following at least one chemotherapy

76 treatment. This is the first report of morphological and follicle developmental

77 similarities between ABVD-treated tissue and the immature human ovary. Further

78 experiments will investigate the basis for the marked increase in follicle density in

79 ABVD-treated tissue.

80

83 **Keywords: ovary/ follicle/ lymphoma/ ABVD/ oocyte**

84

85

86

87 **Introduction**

88

89 The number of follicles in the ovary decreases progressively with age. Treatments

90 such as some chemotherapy agents can accelerate this loss leading to premature

91 ovarian insufficiency (POI) with loss of fertility and estrogen deficiency in female

92 survivors of cancer (Morgan *et al.*, 2012). The likely range of mechanisms of drug-

93 induced ovarian damage has yet to be fully characterised but includes direct damage

94 to growing and non-growing follicles, and loss of growing follicles may lead to the

95 recruitment of dormant follicles to the growing phase which in turn are lost, thus

96 accelerating the depletion of the non-growing pool, ie the ovarian reserve (Meirow *et*

97 *al.*, 2010; Morgan *et al.*, 2012; Kalich-Philosoph *et al.*, 2013).

98 Since the mid-1970s the standard first line treatment for early stage Hodgkin

99 lymphoma (HL) in many countries has been adriamycin, bleomycin, vinblastine and

100 dacarbazine (ABVD) (Bonadonna and Santoro, 1982; Meirow and Nugent, 2001;

101 Meyer *et al.*, 2012). Early stage HL patients receiving ABVD based treatment where

102 involved field radiotherapy does not include the ovaries have a good reproductive

103 prognosis for both fertility and risk of POI (Hodgson *et al.*, 2007, Swerdlow *et al.*,

104 2014). In contrast advanced stage HL patients treated with a drug regimen

105 containing one or more alkylating agents and involved field radiotherapy have a

106 higher prevalence of POI (Behringer *et al.*, 2005), and should therefore be

107 considered for fertility preservation strategies before commencing treatment

108 (Anderson *et al.*, 2015).

109 The purpose of this study was to examine microscopically, ovarian tissue from

110 patients with lymphoma exposed to ABVD chemotherapy and compare this with

111 samples exposed to the combined alkylating chemotherapeutic regime (combined

112 vincristine, etoposide, prednisone, doxorubicin (OEPA) and cyclophosphamide,

113 vincristine, prednisone, dacarbazine (COPDAC) (OEPA-COPDAC), with samples not

114 previously exposed to chemotherapy and with further samples from healthy women

115 to determine whether follicle density, morphology and *in vitro* developmental

116 potential were affected by these chemotherapeutic interventions. Comparing follicle

117 densities across treatments requires identification of changes to non growing follicle

118 (NGF) cortical densities in comparison with those predicted by age related models

119 (Kelsey & Wallace., 2012; Kelsey et al., 2013).In this study we used a recently

120 reported validated age-related model of mean follicle density (MFD) in the ovarian

121 cortex (McLaughlin *et al*., 2015), to compare observations of MFD in tissue obtained

122 after different chemotherapy regimens.

123

124 **Materials and Methods**

125 **Patient Selection**

126 Diagnosis, patient age, chemotherapeutic regimen, anti-Müllerian hormone (AMH)

127 concentrations and time between completion of treatment and biopsy collection are

128 detailed in Table 1.

129 **Ovarian Cortical Tissue**

130 Ovarian biopsies were obtained laparoscopically from 6 adolescents and 7 adults

131 diagnosed with Hodgkin lymphoma and 1 adult diagnosed with non-Hodgkin

132 lymphoma. All patients were undergoing removal of ovarian cortex for fertility

133 cryopreservation either prior to chemotherapy or following relapse of previously

134 treated illness. Protocols for tissue donation for research had Ethical Committee

135 approval (ref 06/S1103/26) and all patients gave informed consent in writing. The

136 mean patient age was 20.2±1.5 years (mean ±SEM) with a range of 12.0 – 30.0

137   years. For analyses patients were divided into 3 groups: those treated with ABVD

138   (aged 16 – 29 years, *n* = 8), those treated with OEPA-COPDAC (aged 14 – 16 years,

139   *n* = 3) and untreated patients or controls (aged 12 – 30 years, *n* = 3). Data were

140   compared with results obtained from contemporaneous ovarian biopsies obtained

141   from adult women undergoing elective Caesarean section (age range 23 – 39 years,

142   *n* = 12) prepared and processed in an identical manner, also obtained with written

143   informed consent and Ethical committee approval (ref 10/S1101/24).

144

145   **Tissue preparation and processing**

146   Fresh ovarian biopsies(ranging in size from 8x5mm and 6x4mm all with variable

147   thickness)were transported to the laboratory in holding medium (Leibovitz medium,

148   Gibco; Life Technologies, Paisley, Renfrewshire, UK supplemented with 2mM

149   sodium pyruvate, 2mM L-glutamine, 3mg/ml human serum albumin, 75mg/ml

150   penicillin G and 50mg/ml streptomycin; all chemicals from Sigma-Aldrich, Poole,

151   UK). Tissue was transferred into fresh pre-warmed (37 ^{o}C) holding medium and

152   examined under a dissecting light microscope. A scalpel and fine forceps were used

153   to remove any damaged or haemorrhagic areas as well as any tissue adhering to the

154   underside of the biopsies to leave only intact cortex in place. Using a scalpel the

155   tissue was divided into fragments of approximately 4 x 2 x 0.5 mm; the number of

156   fragments varied between biopsies. Fragments were fixed in 10% neutral buffered

157   formalin (NBF) for 48h then processed and prepared for staining and microscopic

158   evaluation as previously described (McLaughlin *et al.*, 2014).

159   **Thawing of cryopreserved tissue**

160   Two of the biopsies were cryopreserved by slow freezing (Gosden *et al.*, 1994) and

161   were donated for research at the patients' request. Tissue was thawed as described

162   previously (Anderson *et al.*, 2014), inspected, divided into fragments, fixed and

163   processed for staining and analysis as described above.

164   **Assessment of mean follicle density in ovarian biopsies**

165   Each histological section of every tissue fragment was examined under light

166   microscopy. Follicles were categorised according to their stage of development as

167   previously described (Telfer *et al.*, 2008; McLaughlin *et al.*, 2014). To avoid over-

168   counting, only follicles containing the nucleolus were assessed. The volume of tissue

169   analysed per patient was calculated as described previously (Lass *et al.*, 1997;

170   Anderson *et al.*, 2014). Briefly, tissue volume was calculated as the sum of the area

171   in mm^2 of all tissue sections analyzed per patient, multiplied by 0.006 mm (the

172   thickness of the sections) to give a value in mm^3. The area of each section was

173   measured and mean follicle density was determined by dividing the total number of

174   follicles per patient by the volume of tissue analyzed in mm^3 (Anderson *et al.*, 2014).

175

176   **Evaluation of histology**

177   Evaluation of the tissue sections was performed blinded to the treatment groups.

178   Follicles in freshly fixed and cultured tissue pieces were categorised by

179   developmental stage based on morphology as previously described (McLaughlin *et*

180   *al.*, 2014).Follicle morphological normality was determined by an assessment of the

181   appearance of the oocyte and surrounding cells using the cross-section containing

182   the nucleolus as described previously (McLaughlin and Telfer, 2010, McLaughlin *et*

183   *al.*, 2014). The presence of bi-ovular and binucleate follicles was also noted.

184   The spatial relationship between follicles was also assessed and classified as (1)

185   single i.e. no follicles within 15 μm of the follicle being evaluated, (2) in close

186   proximity i.e. at least one other follicle occurring within 15μm of the follicle being

187 evaluated or (3) direct contact i.e. where 2 or more follicles appeared to share the

188 same basal lamina or the basal laminae of 2 or more follicles abutted. Follicles were

189 classified as occurring in clusters if 5 or more follicles were found in direct contact or

190 close proximity. The presence of naked oocytes with few or no surrounding cells was

191 also noted.

192

193 **Fragment culture**

194 Prior to fixation a number of tissue fragments were selected at random from a sub-

195 section of the ABVD-treated patients (n = 4; age range 23 - 29 years), 1 OEPA-

196 COPDAC-treated patient (16 years), 2 untreated controls (15 years and 30 years)

197 and from obstetric patients (n = 10; age range 23 – 36 years). Between 2 and 6

198 fragments were obtained for each patient, prepared for culture and incubated for 6

199 days then processed for histological evaluation as previously described (McLaughlin

200 *et al.*, 2014).

201

202 **Immunohistochemistry**

203 A number of ABVD-treated, OEPA-COPDAC-treated and control tissue fragments

204 fixed in NBF and embedded in paraffin as described previously (McLaughlin *et al.*,

205 2014) were selected at random and cut in 6µm sections and mounted on charged

206 slides to investigate the expression of the germline marker proteinDEAD box

207 polypeptide 4 (DDX4). Antigen retrieval was performed using 0.01M sodium citrate

208 and endogenous peroxidase activity quenched by 3% hydrogen peroxide in

209 methanol. Tissue sections were incubated in anti-DDX4/MVH ab13840 polyclonal

210 primary antibody (Abcam, Cambridge, UK) overnight at 4 °C. Negative controls were

211 established by replacing the primary antibody with goat serum. On completion of

212   incubation, sections were washed and probed with anti-rabbit secondary antibody

213   labelled with horseradish peroxidase for 30 mins (ABC-Elite Rabbit IgG, Vectastain

214   Elite Kit, PK-6101, Vector Laboratories Ltd, Peterborough, UK). DDX4 was detected

215   using 3, 3'-diaminobenzidine (DAB) peroxidase substrate kit (Vector Laboratories

216   Ltd, Peterborough, UK). Structures were positively identified as germ cells when

217   brown staining was observed within a cell.

218

219   **Statistical analysis**

220   Observed mean follicle densities were compared to predicted mean follicle densities

221   using an age-related model of mean follicle density in the cortex of the human ovary

222   (McLaughlin *et al.*, 2015). Chi-Square Goodness-of-Fit analysis was used to test the

223   null hypotheses that the observations matched predicted MFD. Pearson's product-

224   moment correlation coefficients were also calculated to compare data to the line of

225   identity where predictions exactly match observations. Due to the need for high

226   confidence in the significance of any observed differences between predicted and

227   observed densities, statistical significance was set at the 99% level throughout.

228   Bland-Altman analysis was used to estimate the number of standard deviations away

229   from agreement between observations and predictions using the limits of agreement

230   reported in McLaughlin *et al.* (2015).

231

232   **Results**

233   **Follicle density**

234   The number of follicles and their developmental stage were determined by

235   examining fresh and post-thawed fixed ovarian tissue from 14 previously treated and

236   untreated lymphoma patients and an age-matched group of 12 obstetric patients; a

237 total of 6877 follicles were examined. The total number of follicles counted in each

238 group and the volume of tissue analysed are shown in Table 2. Ages and MFDs for

239 the three groups of lymphoma patients are shown in Fig. 1A, together with age-

240 related predictions taken from McLaughlin *et al.*, (2015). For the three patients who

241 received no chemotherapy we have insufficient evidence to reject the null hypothesis

242 that the observed values for MFD are a perfect fit with predicted values taken from

243 the age-related model derived from data from other subjects receiving no

244 chemotherapy: Chi-square p-value = 0.07; Pearson's product-moment correlation

245 coefficient = 0.999 ($p< 0.01$, Fig. 1B) with the observations within 1.25 standard

246 deviations of agreement between observed and predicted values (Fig. 1C). The

247 three patients who received OEPA-COPDAC chemotherapy had significantly lower

248 observed MFD than predicted: Chi-square p-value < 0.01; Pearson's product-

249 moment correlation coefficient = -0.399 ($p = 0.74$, Fig. 1B) with the observations

250 between 0 and 11 standard deviations lower than the predictions (Fig. 1C).

251 However,the eight patients who had received ABVD chemotherapy had higher

252 numbers of non-growing follicles (160-303/mm^3 compared with samples from

253 healthy women (8-46/mm^3) (Table 2). The ABVD group had significantly higher

254 observed than predicted MFD: Chi-square p-value < 0.001; Pearson's product-

255 moment correlation coefficient = 1.57 ($p = 0.71$, Fig. 1B) with observations between

256 9 and 21 standard deviations higher than the predictions (Fig.1C).

257

258 Time elapsed between completion of chemotherapy regimen and biopsy ranged from

259 1 to 36 months, with six of the eight ABVD-treated patients having tissue collected

260 within 6 weeks and all OEPA-COPDAC patients undergoing biopsy within 9 months

261 of treatment. No correlation was found between the time interval and the MDF

262 observed in tissue treated with either regimen: the marked increase in MFD in

263 ABVD-treated tissues was observed in biopsies taken within 4 weeks of

264 chemotherapy completion and was also present in samples taken up to 36 months

265 after treatment, although the small sample size at the later treatment times does not

266 allow for time after treatment to be robustly tested. The OEPA-COPDAC tissue from

267 two out of three patients showed follicle numbers below that predicted at 6-9 months

268 post treatment. Biopsy tissue was only available from each patient at one time point

269 therefore it was not possible to investigate by histological means whether

270 deterioration or recovery of NGF density occurred over time.

271

272 **Follicle categorisation**

273 The majority of all follicles observed in fixed tissue were non-growing irrespective of

274 illness, treatment or age (Fig. 2A). However ABVD-treated tissue contained a

275 significantly smaller percentage of growing follicles (3.0%) compared to untreated,

276 OEPA-COPDAC-treated and obstetric patients (15.6%, 21.4% and 18.0%

277 respectively; $p< 0.001$) (Fig. 2A).

278 Analysis of oocyte appearance showed that in biopsies collected from untreated,

279 ABVD-treated and obstetric patients, morphological normality was high with >74% of

280 oocytes appearing normal. In contrast less than half of the oocytes in follicles

281 observed in OEPA-COPDAC-treated tissue met the criteria for normality (41.9% in

282 OEPA-COPDAC compared to 76.8% in untreated; 78.4% in ABVD-treated and

283 74.2% in obstetric samples; $p< 0.001$) (Fig. 2C and D).

284

285 **Follicle development in cultured tissue**

286   To investigate the *in vitro* developmental potential of chemotherapy-exposed

287   follicles, tissue fragments from a subset of patients representing each group were

288   cultured for 6 days. It was not possible to culture fragments from every patient due to

289   the limited amount available. A total of 89, 614 and 274 follicles were analysed in

290   cultured tissue obtained from untreated (n = 2), ABVD-treated (n = 4) and obstetric

291   patients (n = 10) respectively. Analysis of cultured tissue fragments from two patients

292   treated with OEPA-COPDAC has been omitted due to extreme follicle degeneration

293   in both patients. Initiation of follicle growth was observed in all of the 3 remaining

294   groups. Post-culture the proportion of growing follicles was 19.9% in ABVD-treated

295   tissue, 41.6% in untreated tissue and 46.3% in obstetric samples (all *P*< 0.001

296   versus uncultured)(Fig. 3A). Development to the secondary stage occurred in both

297   untreated and obstetric groups with 18% and 18.2% of follicles observed reaching

298   this stage respectively whereas very few follicles progressed in the ABVD-treated

299   tissue, comprising only 1.2% of follicles at the secondary stage after culture (Fig 3B

300   and C).

301

302   **Immunohistochemical localization of DDX4**

303   Due to the high density of non-growing follicles observed in ABVD-treated tissue and

304   the presence of clusters, bi-ovular and binucleate follicles, immunohistochemistry

305   was performed to examine whether the germline marker DDX4 could be localized in

306   these structures. Uncultured tissues sections from 9 patients representing all groups

307   were studied; the number of sections per patient was variable due to tissue

308   availability, and the number of follicles per section was also highly variable. Discrete

309   positive DDX4 staining was observed in oocytes of follicles at all stages of

310   development in all groups. DDX4 was also localised to the bi-ovular and binucleate

311 oocytes and clusters of naked oocytes with adjacent or shared oolemmae observed

312 in ABVD-treated tissue. No positive staining was observed in any tissue sections

313 where the primary antibody had been omitted (Fig. 3D).

314

315 **Spatial distribution of follicles**

316 In all groups individual follicles and groups of follicles were distributed unevenly

317 throughout the cortex however the pattern of distribution varied between groups with

318 the majority of follicles occurring discretely (single follicles ≥ 15µm apart) in obstetric

319 tissue (Fig. 4A and B). ABVD-treated and untreated adolescent tissues appeared

320 markedly different from the others examined, with significantly fewer discrete follicles

321 seen and clusters of closely packed follicles (5 or more NGF ≤ 15µm apart) observed

322 in these groups(p< 0.05; ABVD-treated and untreated versus OEPA-COPDAC-

323 treated and obstetric patients(Fig.4A and C).Bi-ovular and binucleate follicles were

324 observed in ABVD-treated tissues and also in the 12 year old untreated patient's

325 tissue comprising between 8-18% of the NGF population. These structures were not

326 observed in the other tissues examined. Follicle clusters often contained naked or

327 partially naked oocytes, which otherwise appeared morphologically normal (Fig 4C).

328

329

330 **Discussion**

331 Ovarian dysfunction and reduced fertility potential can be a consequence of cytotoxic

332 therapy particularly where alkylating agents have been used, with resultant loss of

333 the ovarian reserve (Meirow *et al.*, 2010). In contrast women diagnosed with

334 lymphoma and treated with the gonad-sparing regimen ABVD have a low risk of

335 significant impairment of fertility (Hodgson *et al.*, 2007) or of POI (Swerdlow *et al.*,

336 2014). The impact of chemotherapy on the ovarian reserve is evaluated indirectly by

337 clinical parameters including amenorrhea, AMH and FSH levels (Meirow, 2000;

338 Oktay *et al.*, 2006; Anderson and Cameron, 2011). Post-treatment AMH levels in

339 lymphoma patients clearly show the differential impact of ABVD and alkylating agent

340 based regimens (Decanter *et al.*, 2010) and AMH levels may also be reduced at the

341 time of diagnosis (Lawrenz *et al.*, 2012).   Although early studies showed that

342 chemotherapy reduced the number of antral follicles in the ovary in girls treated for

343 leukaemia (Himelstein-Braw *et al.*, 1978), to the best of our knowledge this is the first

344 quantitative analysis of the direct effect of chemotherapy treatment on density of the

345 ovarian reserve in lymphoma patients and the impact of the different chemotherapy

346 regimens on morphology and *in vitro* developmental potential of follicles. In this study

347 we have identified and quantified differences in the non-growing follicle population of

348 treated and untreated lymphoma patients. The observed MFD of untreated

349 lymphoma patients were close to the densities predicted by an age-related model

350 indicating that the disease itself is not implicated in the variations of the ovarian

351 reserve observed in the chemotherapy-treated groups.

352 Treatment regimens containing alkylating agents such as cyclophosphamide are

353 known to lead to POI via a direct or indirect reduction in the NGF population (Oktem

354 and Oktay, 2007; Meirow, 2000; Meirow *et al.*, 2010).Our finding that patients treated

355 with the OEPA-COPDAC regimen had lower than predicted MFDs confirms and

356 quantifies this, although the MFD in this small group varied from very low to close to

357 average for age. Further analysis of the degree of loss is not possible without

358 knowing pre-treatment values. In this study patients treated with OEPA-COPDAC

359 were all teenagers (14, 15 and 16 years) at the time of tissue collection, which was

360 6-9 months after completion of chemotherapy. Of the 3 patients included in this study

361 treated with OEPA-COPDAC one was diagnosed with reduced ovarian reserve

362 based on having regular menstrual cycles but undetectable AMH levels one year

363 after completion of treatment and another was diagnosed with POI 6 years post

364 chemotherapy.

365 Surprisingly we found a striking and statistically highly significant increase in follicle

366 number and MFD after ABVD chemotherapy. All eight ABVD patients had higher

367 follicle counts (Table 2) and a markedly higher follicle density than predicted (Fig.

368 2C).Despite the well reported variation of follicle density between and within human

369 cortical biopsies follicles (Kohl *et al.*, 2000; Qu *et al.*, 2000; Poirot *et al.*, 2002;

370 Schmidt *et al.*, 2003; McLaughlin *et al.*, 2015), all ABVD-treated samples consistently

371 showed an increase in the NGF population whereas this was not seen for any of the

372 other groups or individual biopsies. We initially considered that this increase might

373 be attributed to a reduction in ovarian volume during treatment as all treatments

374 would result in an initial reduction in ovarian volume because of the loss of large

375 follicles. However, MFD is based on volume of ovarian cortex, not whole ovary and

376 there is no evidence to support a differential effect on ovarian cortex volume by any

377 treatment. Additionally, these samples were collected 4 weeks to 36 months after the

378 completion of treatment with resumption of follicular growth (indicated by regular

379 menses) in those with longer intervals and there was no apparent relationship

380 between increased follicle number/MFD and interval since treatment. The observed

381 differences between ABVD MFD and control data is between 9-21 standard

382 deviations (Figure 1C) and so a reduction in cortical volume would need to be of that

383 order of magnitude. There are no clinical data/observations to support such a degree

384 of shrinkage.

385   The underlying mechanism for an increase in MFD after ABVD treatment remains to

386   be established. An alternative explanation may be that this treatment has resulted in

387   new oocytes/follicles being formed. Putative germline stem cells or oogonial stem

388   cells, which may be capable of regenerating the NGF population under perturbed

389   conditions have been identified within the adult human ovary (White *et*

390   *al.*,2012;Dunlop *et al.*, 2013;Hanna and Hennebold, 2014). It is possible that the

391   ABVD combination or specific components activate these cells to form oocytes or

392   oocyte like structures. Recent studies have shown that mesenchymal stem cells are

393   sensitive to bleomycin treatment (Nicolay et al., 2016) but nothing is known about

394   how these drugs affect putative germline stem cells and other ovarian cells.

395   We also observed that post-ABVD tissue contains follicle clusters, many containing

396   bi-ovular and binucleate follicles, a feature more commonly associated with the

397   prepubertal ovary (Anderson et al., 2014). Follicles with more than one oocyte are

398   reported during fetal development and in early life in many mammalian species

399   (Papadaki, 1978; Telfer and Gosden 1987; Silva-Santos and Seneda, 2011) but are

400   much rarer in adults (Turkalj *et al.*, 2013) and may be preferentially lost with

401   abnormal follicles during childhood (Anderson *et al.*, 2014). No bi-ovular or

402   binucleate follicles were observed in tissue from healthy women, or following OEPA-

403   COPDAC treatment, highlighting that this difference inNGF patterning in the cortex of

404   tissue is a result of the specific chemotherapy treatment. Furthermore, the *in vitro*

405   developmental potential of ABVD-treated tissue showed differences compared to

406   control tissue, with limited follicle development, comparable to that from prepubertal

407   girls (Anderson *et al.*, 2014). We suggest that the lack of development in ABVD-

408   treated tissue may be attributed to the inhibitory effect exerted by the high density of

409   primordial follicles present (Da Silva-Buttkus *et al.*, 2009). Initiation of follicle growth

410   was observed in the obstetric patient cohort supporting the findings of previous

411   studies (Anderson*et al.*, 2014, McLaughlin *et al.*, 2014).

412   In summary this study demonstrates that ABVD treatment does not diminish the

413   ovarian reserve and may paradoxically increase it. Other significant features such as

414   the presence of bi-ovular and binucleate oocytes and clustering are increased. In this

415   respect, ABVD-exposed tissue is similar to that from prepubertal girls, and this

416   similarity is also reflected in its reduced capacity for follicle development *in vitro*. The

417   number of patients analysed is small and so interpretation should be cautious.

418   However, the data presented here have highlighted a phenomenon that has not

419   been previously reported. Further investigation is required to elucidate the

420   mechanism by which the ovarian reserve is affected by ABVD treatment, and the

421   consequences for later fertility and reproductive lifespan.

584 **Legends to Figures**

585 **Figure 1 (A).** Observed and predicted human mean follicle density (MFD). Black

586 dots represent model-predicted values from ages 10 through 50 years. Blue dots

587 denote MFDs of patients that did not receive chemotherapy, green dots patients that

588 received combined vincristine, etoposide, prednisone, doxorubicin (OEPA) and

589 cyclophosphamide, vincristine, prednisone, dacarbazine (COPDAC) (OEPA-

590 COPDAC) and red dots patients that received adriamycin, bleomycin, vinblastine

591 and dacarbazine (ABVD). All tissue was uncultured. **(B)** Pearson product-moment

592 correlation. The line of identity represents the idealised confluence of observed and

593 predicted values. Blue dots indicate observed against predicted MFD for 3 untreated

594 patients. **C)** Bland-Altman Plot. The x-axis represents means (i.e. half the sum of

595 observed and predicted MFD values); the y-axis represents the differences (i.e.

596 predicted MFD values subtracted from observed values). The solid horizontal line

597 shows no trend between means and differences. Blue dots denote difference from

598 predicted MFD for untreated patients; these are between 0 and 1.25 standard

599 deviations (i.e. between 0 and 16 follicles) below the zero predicted difference.

600 Greens dots denote difference from predicted MFD for 3 OEPA-COPDAC-treated

601 patients' chemotherapy protocol; these are between 1 and 11 standard deviations

602 (i.e. between 12 and 132 follicles) below the zero predicted difference. The red dots

603 denote difference from predicted MFD for 8 ABVD-treated patients; these are

604 between 9 and 21 standard deviations (i.e. between 108 and 250 follicles) above the

605 zero predicted difference.

606 **Figure 2 (A)** Distribution of follicle classes (as percentage of total) in fixed ovarian

607 tissue from untreated, combined vincristine, etoposide, prednisone, doxorubicin

608 (OEPA) and cyclophosphamide, vincristine, prednisone, dacarbazine (COPDAC)

609 (OEPA-COPDAC) and adriamycin, bleomycin, vinblastine and dacarbazine (ABVD)

610 treated girls and adults, and obstetric patients. 469, 903, 5001 and 504 follicles were

611 classified in the four groups, respectively. Blue: non-growing follicles; red: primary

612 follicles; green: secondary follicles. (**B**) Photomicrographs of non-growing follicles in

613 a 22 year-old lymphoma patient treated with ABVD (main image and inset). Scale

614 bars 30μm inset and 50μm main image.**(C)** Assessment of oocyte appearance within

615 growing and non-growing follicles in fixed tissue. Fewer morphologically normal

616 oocytes were observed in OEPA-COPDAC-treated tissue compared to other groups

617 ($p<0.001$) (**D**) Photomicrograph of morphologically abnormal follicles in fixed tissue

618 donated by a 16 year-old OEPA-COPDAC-treated patient (main image and

619 inset).Scale bars 30μm inset and 50μm main image.

620 **Figure 3(A)**. Distribution of follicle classes (as percentage of total) in ovarian tissue

621 cultured for 6 days from untreated (n=2) and adriamycin, bleomycin, vinblastine and

622 dacarbazine (ABVD) treated girls and adults (n=4), and obstetric patients (n=10).

623 Blue: non-growing follicles; red: primary follicles; green: secondary follicles. A total of

624 89, 614 and 274 follicles are classified in the three groups, respectively. **(B)**

625 Photomicrograph of *in vitro* activated follicles in 23 year-old obstetric tissue. Scale

626 bar 60μm. **(C)** Photomicrograph of non-growing follicles in 23 year-old ABVD-treated

627 tissue after incubation for 6 days. Scale bar 60μm.**(D)** Photomicrograph showing

628 immunohistochemical detection of DDX4 in 22 year old ABVD-treated ovarian cortex.

629 (i) Brown staining indicating present in all structures morphologically identified as

630 germ cells. (ii) Negative control where primary antibody was omitted. Scale bar =

631 60μm.

632 **Figure 4 (A)**. Incidence (i.e.number of observations) of single (blue) and clustered

633 (red) follicles as percentage of total in fixed ovarian tissue from untreated, combined

634 vincristine, etoposide, prednisone, doxorubicin (OEPA) and cyclophosphamide,

635 vincristine, prednisone, dacarbazine (COPDAC) (OEPA-COPDAC) treated,

636 adriamycin, bleomycin, vinblastine and dacarbazine (ABVD)-treated girls and adults,

637 and obstetric patients. **(B)** Photomicrograph of non-growing follicles (NGFs) in fixed

638 tissue from 36 year-old obstetric tissue. Dashed blue lines indicating a distance of

639 ≤15µmbetween follicles. Scale bar 100µm. **(C)** Photomicrograph of non-growing

640 follicles in fixed tissue 22 year-old ABVD-treated tissue. Purple circles indicate areas

641 of clustered NGFs within 15µm or less of each other. Scale bar = 60µm. Inset: non-

642 growing bi-ovular follicle in ABVD-treated tissue. Scale bar 25µm in inset

643
